

Switching the DV from Δ to absolute post log p(marker) collapses the secondary finding

Per-cell Spearman $\rho \pm 95\%$ bootstrap CI. Left: absolute post log p(marker), the operational leakage measure.

Right: $\Delta = \text{post} - \text{base}$, the previously reported metric ($\rho(\text{base}, \Delta) \approx -0.93$ at anchor — Δ is anti-correlated with base prior by ceiling saturation). Orange = CI crosses zero. Three cells (+pos personas = 2, +pos personas = 4, +neg personas = 8) are degenerate by the §4.2.5 cosine-spread guard and skipped.
