

Cosine → transfer gradient by transformation group (#474 localized arm, ep1) [length-partial rho]

Mean transfer per cosine-similarity quintile. Higher base-model cosine similarity → more marker transfer, monotone in every group. The strict persona-to-persona slice (both endpoints a persona, n=20) is rho=+0.35 but underpowered (p=0.13); the persona panel here counts any cell with a persona endpoint.
