

The sign of the role-vs-system gap flips between epochs

$d = \log P_{\text{system}} - \log P_{\text{role}}$, paired per seed (averaged over pirate, villain), bootstrapped ($N=10,000$) over 5 seeds. Positive d means role leaks LESS. At $E=1$, d goes the other way at both slots; by $E=3$, d crosses zero and matches the saturated edge from the parent run.
