

How well does each predictor rank features by how well the map predicts them?
open = pooled · filled = matched on firing rate (per-token decile × per-answer tercile) · n = 120,716 features

c = P(the feature with the higher predictor value is the better-predicted one), over pairs the predictor separates.
For a binary predictor this is exactly the ordinary AUROC; R^2 is never thresholded. MATCHED forms pairs only within cells of per-token firing decile × within-decile per-answer activity tercile (30 cells, ~4,000 features each). Every value is MARGINAL: firing rate is controlled, the other predictors are not (pairwise correlations reach 0.85). No confidence intervals.
