

The fixed-stub probe pins every persona near zero probability

Each persona's marker log-probability under the off-distribution fixed-stub probe (circles) vs. on the model's own answers (diamonds). 16 of the 27 non-source personas sit within half a nat of the source's -18.4 (a few sink lower, to -27); the on-policy probe lifts the source to $p = 0.72$.
