

The role-vs-system gap is persona-asymmetric at the default slot — averaging hides it

$d = \log P_{\text{system}} - \log P_{\text{role}}$, paired per seed, per persona (NOT averaged). Bootstrapped (N=10,000) over 5 seeds. Positive d means role leaks LESS. Wrong-slot gap (top row) moves with E in the same direction for both personas but inside the saturated floor. Default-slot gap (bottom row) is opposite-signed between pirate and villain at E=5 — averaging would cancel the structure.
