

Result 2 (P-B protocol), persona-vector spread-flagged view: reads across evaluation regimes, hatched where the DV spread gate fails

P-B (LODO): the readout trains on an 80% group-level slice of every trait-eliciting dataset EXCEPT one held out whole, plus the judged WildChat train split; one fit per holdout, and the 'completely OOD' bar is each fit's own held-out dataset.
The context->answer MAP is identical under both protocols: fit once per behaviour on the ADD pool (generic WildChat + the `train` eliciting corpus) and frozen. The persona-vector projection arms shown here are NOT label-consuming -- they project onto `r_B` built from the judge-filtered synthetic extraction set -- so they are bit-identical across P-A and P-B except in the in-distribution regime, where P-A reads `train` out-of-fold and P-B reads the 20% held-in slice (different eval subsets, not a LODO effect).
Bars are the mean over spread-PASSING runs in the regime; error bars are the committed bootstrap CI for single-rung regimes and the s.e.m. across rungs for multi-rung ones. Hatched + muted = every rung in that cell FAILED the DV spread gate ($sd \geq 1.0$ and bottom/top bin ≤ 0.80 on a 0-100 DV; 0-1 binary DVs rescaled) -- kept for completeness, not interpretable. Spread failures: evil hhrt / toxicchat / evil_pair / wildchat_rung.
Only the CONTEXT-based variant is scored (variant=context_end); the prefix-end arm is a stated scope deviation inherited from the parent round. Mapping is LINEAR throughout; no MLP or kernel arm.
n_eval per behaviour x regime --
evil: synthetic 1,000 [5/5 rungs kept]; generic chat 2,085 [0/5 rungs kept]; in-distribution 5,810 [5/5 rungs kept]; completely OOD 2,033 [2/5 rungs kept]
sycophancy: synthetic 1,200 [6/6 rungs kept]; generic chat 2,490 [6/6 rungs kept]; in-distribution 19,410 [6/6 rungs kept]; completely OOD 3,916 [6/6 rungs kept]
hallucination: synthetic 400 [2/2 rungs kept]; generic chat 822 [2/2 rungs kept]; in-distribution 6,700 [2/2 rungs kept]; completely OOD 7,188 [2/2 rungs kept]
