

Adapter log-prob saturates in-trained; ΔG varies with base-slot difficulty

n = 50 per cell, 95% bootstrap CI. Left: implant strength varies across arms (21 $\rightarrow$ 22 $\rightarrow$ 14 $\rightarrow$ 7 nats); k=3 implants weakest. Right: cond2_k1's +24.5 nat at the default is near-ceiling — yet argmax-emission there is only 26% (see hero figure). The implant-strength gradient and the base-slot log-prob (which spans ~7 to 26 nats across shapes) both confound any ΔG cross-arm leaderboard.
