

At E=1 (closest to resolution), the role-vs-system gap REVERSES the parent's saturated +1-nat direction

$d = \log P(\text{system_arm}) - \log P(\text{role})$ at the wrong-persona probe, paired per seed. Negative d = role leaks MORE. Errorbars = 95% bootstrap CI over 5 seeds. At E=1 all 4 cells clearly clear zero on the negative side with 100% per-seed sign-agreement; as E grows the trajectory drifts toward the saturated #529 sign-mixed regime.
