

Does the cosine signal survive across arms and epochs?

Length-partial Spearman rho on the NON-stylized panel

LoRA checkpoint (training epochs)

- cosine L21 · positives-only · (vs ΔG)
- cosine L21 · positives-only · (vs trained logP, base-prior-safe)
- JS · positives-only · (vs ΔG)
- cosine L21 · localized (pos+neg) · (vs ΔG)
- cosine L21 · localized (pos+neg) · (vs trained logP, base-prior-safe)
- JS · localized (pos+neg) · (vs ΔG)

Positive cosine rho = higher base-model similarity predicts more transfer among non-stylized pairs. 'sat' marks points where the non-stylized panel is >50% saturated (ΔG number suspect; read the dotted trained-logP line).
