

What survives adjusting for how often a feature fires?

114,980 SAE features (BatchTopK k=64, resid_post layer 19) | held-out R^2 from RIDGE fits only — no nonlinear arm exists at this width | R^2 display-clipped at -1 | R^2 is the #1738 multi-turn corpus context arm; covariates are #1482 single-turn

error bars: percentile 95% CI over 2,000 bootstrap draws (ranks fixed at the full sample, draws reweight them) — at $n = 114,980$ they are narrower than the markers; rows sorted by $|\text{partial } \rho|$
