

Controlling for implantation flips the role arm's small average-leakage advantage

Bare-word install-step grid (#533). Right panel: per-seed leakage minus implantation (both marker log P, trained – base). Caveat: at $s \geq 60$ the own-slot trained log P is exactly 0 for BOTH arms (implant saturated, per-seed std = 0) — the ~1-nat gap is a base-prior difference, which this subtraction inherits.
