

Pooled vs stratified Shapley decomposition

113,262 features; 22 blocks after collapsing collinearity at $|\rho| \geq 0.9$ | REAL TARGET - dense context to SAE feature map, ridge_mean arm (#1482 single-turn corpus, 121,111 scored; covariates same corpus)

Shapley sits between two endpoints by construction: a block ALONE over-counts (the set sums above the total) and its UNIQUE contribution when added last under-counts (sums below). A wide bracket means the block shares variance with others. Split-half share agreement: half1 rho=+0.998, half2 rho=+0.999. Uncertainty is split-half, not bootstrap.
