

k=1 demos teach the behavior — k=3 demos require marker-bearing demos

Copy-vs-implant control. n=50 per cell. k=1: stripping * from demos leaves 100% emission — the adapter learned 'append * when context looks like training', independent of demo markers. k=3: 100% emission in-trained with markers, but 0% both when demos go away AND when demos are present with * stripped — so the cue is the marker-bearing demo, not mere demo presence.
