

Per-probe ΔG — the k=1 demo-free split is an argmax knife-edge

12 cells $\times$ 50 probes. Most cells sit near a ΔG ceiling (~21-26 nats); the k=1 in-trained and demo-free cells show real dispersion; k=3 sits well below. The k=1 demo-free violin has 5 of 37 NON-argmax probes above $\Delta G = 27$ nats — * carries near-equal log-mass to its argmax competitor, and small distribution shifts flip emission.
