

#474 localized arm, ep1: cosine & JS vs marker transfer  $\Delta G$  — persona vs non-persona prompts (quintile means)

Columns: persona-prompt cells ( $\geq 1$  Class-A persona endpoint) vs non-persona cells (both endpoints query-wrap / format / register, no persona). Rows: JS divergence (top) vs layer-21 cosine similarity (bottom). DV =  $\Delta G$ , plain Spearman. The key cell is bottom-right: among pure surface-form variations cosine still predicts transfer ( $\rho \approx +0.55$ ) while JS is null ( $\rho \approx -0.14$ ).
