

The persona-vectors synthetic suite's correlations are mostly the positive-vs-negative instruction contrast

Each arm scored three ways on the SAME 200 suite contexts: pooled over both instruction polarities, then within each 100-context half alone. Every arm's pooled value collapses when the polarity contrast is removed. Evil's negative half has zero DV variance (all 100 contexts score 0), so within-half rho is undefined there.
